## 1 Applications of SVD: least squares approximation

We discuss another application of singular value decomposition (SVD) of matrices. Let  $a_1, \ldots, a_n \in \mathbb{R}^d$  be points which we want to fit to a low-dimensional subspace. The goal is to find a subspace S of  $\mathbb{R}^d$  of dimension at most k to minimize  $\sum_{i=1}^n \left( \operatorname{dist}(a_i, S) \right)^2$ , where  $\operatorname{dist}(a_i, S)$  denotes the distance of  $a_i$  from the closest point in S. We first prove the following.

**Claim 1.1** Let  $u_1, \ldots, u_k$  be an orthonormal basis for S. Then

$$(\operatorname{dist}(a_i, S))^2 = \|a_i\|_2^2 - \sum_{j=1}^k \langle a_i, u_j \rangle^2.$$

Thus, the goal is to find a set of k orthonormal vectors  $u_1, \ldots, u_k$  to maximize the quantity  $\sum_{i=1}^n \sum_{j=1}^k \langle a_i, u_j \rangle^2$ . Let  $A \in \mathbb{R}^{n \times d}$  be a matrix with the  $i^{th}$  row equal to  $a_i^T$ . Then, we need to find orthonormal vectors  $u_1, \ldots, u_k$  to maximize  $||Au_1||_2^2 + \cdots + ||Au_k||_2^2$ . We will prove the following.

**Proposition 1.2** Let  $v_1, \ldots, v_r$  be the right singular vectors of A corresponding to singular values  $\sigma_1 \ge \cdots \ge \sigma_r > 0$ . Then, for all  $k \le r$  and all orthonormal sets of vectors  $u_1, \ldots, u_k$ 

$$||Au_1||_2^2 + \cdots + ||Au_k||_2^2 \le ||Av_1||_2^2 + \cdots + ||Av_k||_2^2$$

Thus, the optimal solution is to take  $S = \text{Span}(v_1, \dots, v_k)$ . We prove the above by induction on k. For k = 1, we note that

$$||Au_1||_2^2 = \langle A^T A u_1, u_1 \rangle \le \max_{v \in \mathbb{R}^d \setminus \{0\}} \mathcal{R}_{A^T A}(v) = \sigma_1^2 = ||Av_1||_2^2.$$

To prove the induction step for a given  $k \le r$ , define

$$V_{k-1}^{\perp} = \left\{ v \in \mathbb{R}^d \mid \langle v, v_i \rangle = 0 \ \forall i \in [k-1] \right\}.$$

First prove the following claim.

**Claim 1.3** Given an orthonormal set  $u_1, \ldots, u_k$ , there exist orthonormal vectors  $u'_1, \ldots, u'_k$  such that

- $u'_{k} \in V_{k-1}^{\perp}$ .
- Span  $(u_1, \ldots, u_k)$  = Span  $(u'_1, \ldots, u'_k)$ .
- $\|Au_1\|_2^2 + \dots + \|Au_k\|_2^2 = \|Au_1'\|_2^2 + \dots + \|Au_k'\|_2^2.$

**Proof:** We only provide a sketch of the proof here. Let  $S = \text{Span}(\{u_1, \dots, u_k\})$ . Note that  $\dim(V_{k-1}^{\perp}) = d - k + 1$  (why?) and  $\dim(S) = k$ . Thus,

$$\dim \left(V_{k-1}^{\perp} \cap S\right) \geq k + (d-k+1) - d = 1.$$

Hence, there exists  $u_k' \in V_{k-1}^{\perp} \cap S$  with  $||u_k'|| = 1$ . Completing this to an orthonormal basis of S gives orthonormal  $u_1', \ldots, u_k'$  with the first and second properties. We claim that this already implies the third property (why?).

Thus, we can assume without loss of generality that the given vectors  $u_1, \ldots, u_k$  are such that  $u_k \in V_{k-1}^{\perp}$ . Hence,

$$||Au_k||_2^2 \le \max_{\substack{v \in V_{k-1}^{\perp} \\ ||v||=1}} ||Av||_2^2 = \sigma_k^2 = ||Av_k||_2^2.$$

Also, by the inductive hypothesis, we have that

$$||Au_1||_2^2 + \cdots + ||Au_{k-1}||_2^2 \le ||Av_1||_2^2 + \cdots + ||Av_{k-1}||_2^2$$

which completes the proof. The above proof can also be used to prove that SVD gives the best rank k approximation to the matrix A in Frobenius norm. We will see this in the next homework.

## 2 Bounding the eigenvalues: Gershgorin Disc Theorem

We will now see a simple but extremely useful bound on the eigenvalues of a matrix, given by the Gershgorin disc theorem. Many useful variants of this bound can also be derived from the observation that for any invertible matrix S, the matrices  $S^{-1}MS$  and M have the same eigenvalues (prove it!).

**Theorem 2.1 (Gershgorin Disc Theorem)** Let  $M \in \mathbb{C}^{n \times n}$ . Let  $R_i = \sum_{j \neq i} |M_{ij}|$ . Define the set

$$Disc(M_{ii}, R_i) := \{z \mid z \in C, |x - M_{ii}| \le R_i\}.$$

*If*  $\lambda$  *is an eigenvalue of* M*, then* 

$$\lambda \in \bigcup_{i=1}^n \operatorname{Disc}(M_{ii}, R_i).$$

**Proof:** Let  $x \in \mathbb{C}^n$  be an eigenvector corresponding to the eigenvalue  $\lambda$ . Let  $i_0 = \operatorname{argmax}_{i \in [n]} \{|x_i|\}$ . Since x is an eigenvector, we have

$$Mx = \lambda x \quad \Rightarrow \quad \forall i \in [n] \quad \sum_{j=1}^{n} M_{ij} z_j = \lambda x_i.$$

In particular, we have that for  $i = i_0$ ,

$$\sum_{j=1}^{n} M_{i_0 j} x_j = \lambda x_{i_0} \implies \sum_{j=1}^{n} M_{i_0 j} \frac{x_j}{x_{i_0}} = \lambda \implies \sum_{j \neq i_0} M_{i_0 j} \frac{x_j}{x_{i_0}} = \lambda - M_{i_0 i_0}.$$

Thus, we have

$$|\lambda - M_{i_0 i_0}| \le \sum_{j \ne i_0} |M_{i_0 j}| \cdot \left| \frac{x_j}{x_{i_0}} \right| \le \sum_{j \ne i_0} |M_{i_0 j}| = R_{i_0}.$$
